ACKNOWLEDGEMENTS

The author wishes to acknowledge the participation and guidance of several individuals during the development of this computer simulation model. Brigadier General (Ret) Charles Ostrom and Mr. Bernard M. Davall, with their experience and background in both logistics and simulation, guided the development of the model. Mr. Don S. Mackey provided the extensive data base needed for the realistic application outlined in this report.

COMPUTER SIMULATION MODEL OF AN AMMUNITION SUPPLY POINT:

ISSUE OPERATIONS

INTRODUCTION

A topic of interest to the US Army Missile and Munitions Center School (USAMMCS) and other members of the US Army logistics community, is the evaluation of changes in TOE, training and doctrine and their effects upon ammunition supply at the company level. At the request of the USAMMCS and in support of the US Army Human Engineering Laboratory Forward Area Supply & Transfer (USA HELFAST) studies, the US Army Human Engineering Laboratory (USAHEL) developed a stochastic computer simulation model for the issue operations of an Ammunition Supply Point (ASP). The model is in a form useful for the study of the effects of personnel, organization, equipment and physical layout upon mission performance. The ASP's are direct support supply points normally positioned in the Corps area near the rear boundary of combat divisions. The using units pick up ammunition in their own vehicles. The ASP's are routinely supplied on a scheduled basis from storage depots in the rear area.

The USA HELFAST field tests determined time distributions for ammunition handling (i.e., loading, transfer and unloading) involving material handling equipment for different ammunition types, cargo carriers and weather conditions. The simulation model uses the time distributions from the field tests for the ammunition handling tasks within the ASP. The model has been used to study ASP operations for critical areas which require further testing and evaluation. The model could be used to evaluate changes in TOE, training and doctrine. Furthermore, the model is easily extended to other areas of the US Army logistical system in future studies by the USAHEL and other members of the US Army logistical community.

The simulation program is written in the Fortran language and uses the GASP simulation programs. The model simulates an ammunition company in support of 14 of 29 battalions of a reinforced Armored Division during the second day of a determined defense. The ammunition expenditures are at the maximum rate, and the supported units replace their commodity loads by truck convoys back to the ASP. The model processes the convoys and trucks through the various sections of the ASP as they arrive from the supported units. Statistics are collected during the simulation on the queues, service times and idle times for each service point; i.e., vehicle inspection, office, field storage units, etc., within the ASP. The ammunition handling times are computed from normal [random] distributions. The simulation is run for a 24-hour period. The simulation can be repeated several times for a Monte-Carlo analysis.

The program simulates the operations of an TOE 9-38-H3 Ammunition Handling Company at strength level 1 and equipment level 1 as an acceptable baseline. Ammunition Company operations follow FM 9-38, Conventional

Ammunition Unit Operations, June 1970, with Change 1, 23 March 1973 and Change 2, 10 September 1976. Several noncombat essential operations, needed only for peace time accountability, were deleted following consultation with USAMMCS and USAHEL (retired) military personnel.

Ammunition supply doctrine, as defined in FM 9-6 (under revision), has each unit's resupply-convoy move from the battalion trains area, via the Division Ammunition Office (DAO), to the ASP. Return to the battalion trains is by the most direct route. The operation of the DAO was not modeled in this report as it is strictly clerical, but can be added later. Doctrine states that a division is supported by two ASP's and the model ASP supports half a division plus half the attached reinforcing battalions. The ASP is staffed by one Ammunition Company, TOE 9-38H3.

The ammunition supply demand placed on the ASP is determined by the using units; i.e., the combat and combat support battalions and their expenditures. The augmented armored division is described in Table 2 of Appendix F, Munitions System Support Structure, Volume I, Final Draft, April 1978, by the USAMMCS. A combat engineer battalion was added to the augmentation, and aviation, air defense and engineers were added within the division. Table 1 lists the number and type of units supported, the resupply vehicles and the number of convoys over a 24-hour period.

TABLE 1

Units Supported

Type-Battalion	No.	Resupply Vehicle	Trucks/ Convoy	Number of Convoys (24-Hour Period)
1. Mech Inf	3	GOER	2	2
2. Tank	3	GOER	3	2
3. 155 howitzer	3	GOER	12	3
4. 8-inch howitzer	2	GOER	8	3
5. ADA (Chaparral)	1	5-ton truck	5	1
6. Combat Engr	1	2-1/2-ton truck	13	4
7. Combat Avn	<u>1</u>	5-ton truck	6	<u>2</u>
Totals:	14			34

NOTE: 34 convoys equals: 186 GOERS
17 5-ton trucks
52 2-1/2-ton trucks
255 vehicle per 24 hours

NOTE: Distance [in km] from battalion trains to ASP:
To ASP - 39 to 67
From ASP - 30 to 55

The ASP and supported units were located in the following combat scenario: The terrain for modeling and the troop list were based on SCORES, Europe I, Sequence 2 Alpha. Since SCORES is not primarily logistical in orientation, there were further alterations. The US Army Materiel Systems Analysis Activity (AMSAA) was consulted to locate battalion trains for all battalions in the table. The covering force has been driven in and all troops were positioned on or behind FEBA for the second day of a determined defense. AMSAA also sited the Division Ammunition Office (DAO), the division airfield, and the two ASP's in support of the division. All personnel involved in these modifications, both in the Tactical Operations Analysis Office of AMSAA and in USAHEL, are retired military.

The supply demand on the ASP is determined by the transportation request presented by a using unit's convoy, and the number of times each unit sent out a resupply convoy during the 24-hour period. The transportation request is determined by three factors: (1) rate of expenditure (consumption data) for a determined defense, (2) basic load of the unit, and (3) transportation available within the unit for resupply.

The consumption data by unit type is extracted from US Army Logistics Planning Factors (JSCAP FY 80), and obtained from the Operations Analysis Directorate, Planning Factors Management Division, US Army Logistics Center (USALC). The size of the basic load is defined primarily in FM 101-10-1, July 1976. The transportation assumed available for ammunition resupply purposes is listed in the unit TOE.

A few ground rules for assembling convoys were set up after consulting with combat arms and combat support officers at Aberdeen Proving Ground. The unit uses a minimum number of daily convoys to the ASP so as to maintain command control with reliable convoy commanders and able map readers. One replenishes the basic load when 25-30% is expended. Combat aviation receives its logistic support at the division airfield and is resupplied by surface means. Project materials for engineer operations are drawn about four times a day. These rules may not be doctrine but are validated by such diverse considerations as combat experience, maneuver experience, map reconnaissance, and equipment availability.

Consumption data from USALC had to be expanded to cover bulk allotment items (as hand grenades and pyrotechnics), project materials (as mines and demolitions), and small rockets and guided missiles. Generally, FM 101-10-1 cited previously was the authority but Chaparral and Redeye data were generated locally at four missiles/Chaparral system per day and two missiles/Redeye team per convoy. No day of fire or per day of supply figure for air defense missiles has been officially defined.

The physical layout of the ASP is determined by the terrain and the quantity and types of ammunition stored in support of the using units. The ASP layout usually consists of at least the following sections: (Figure 1) vehicle assembly area, ASP operations control office, three ammunition storage sections, and a vehicle holding area, as well as segregation and demolition areas. The three storage sections contain the same types and amounts of ammunition as practicable. One section is used to issue and

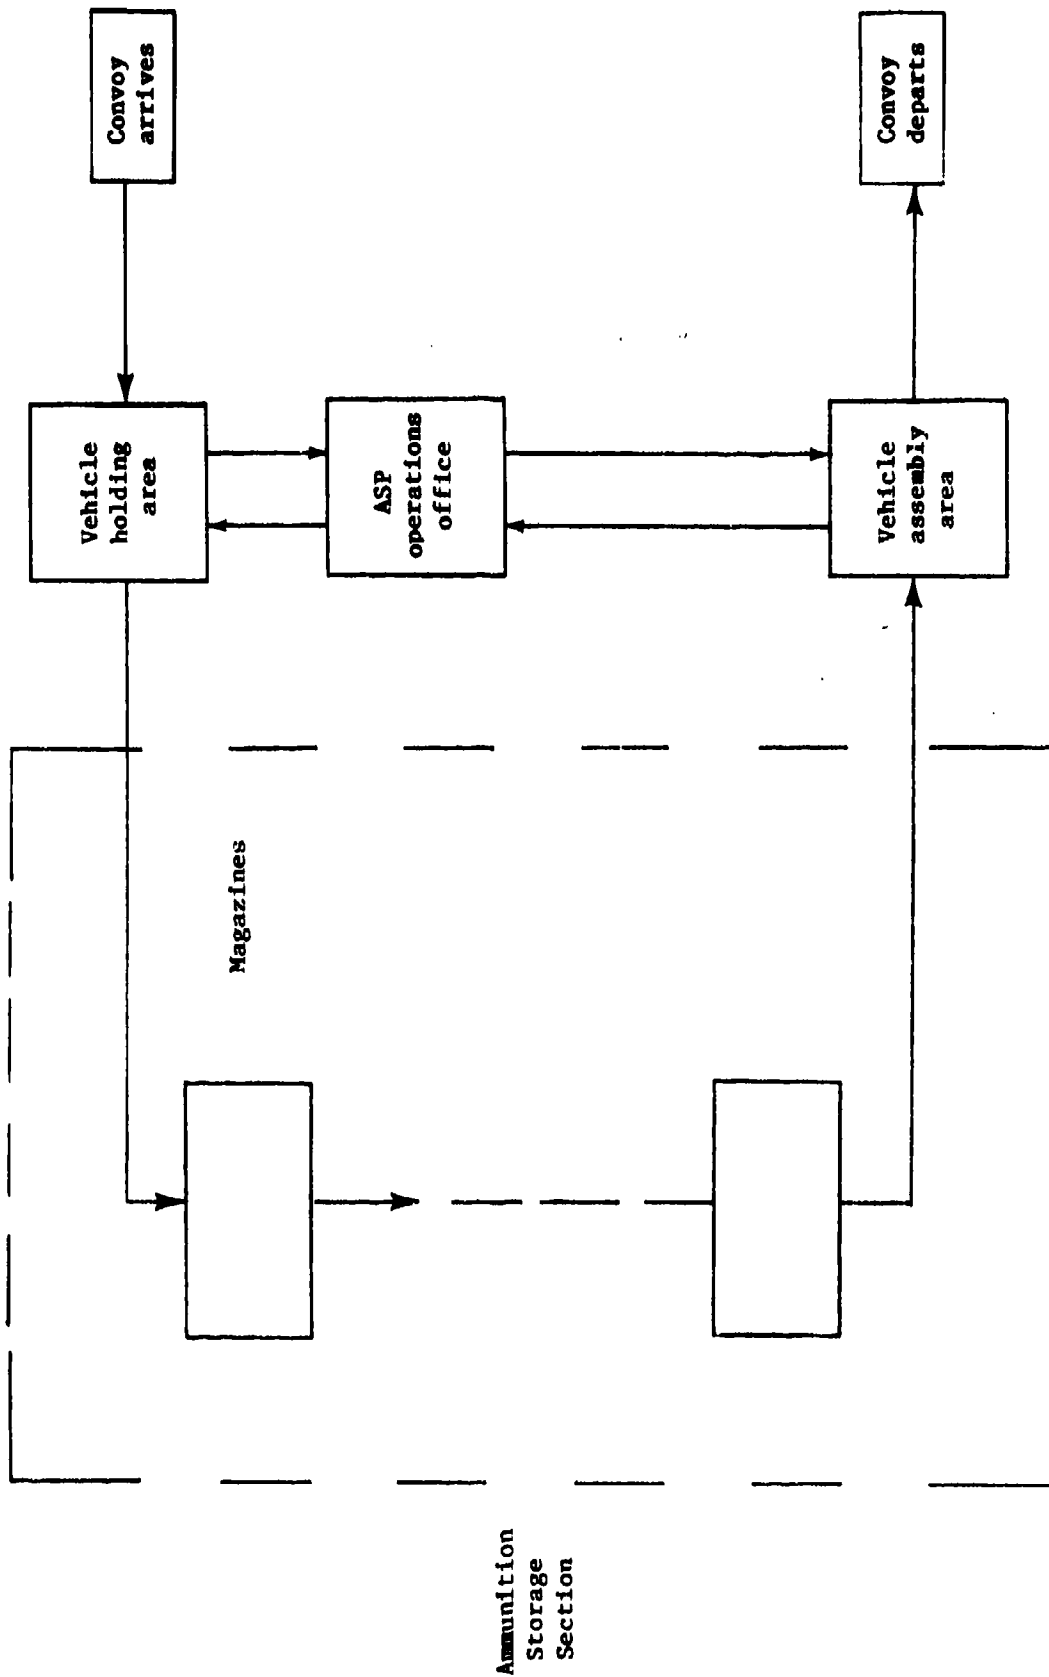

Figure 1. Layout of an ASP.

store ammunition and the other two for inventory and maintenance. These operations are rotated on a daily basis among the three sections.

The map layout is a "school solution" to Problem Sheet, "Storage of Ammunition in the Theater of Operations," USAMMCS, file number C20E-028P03, map sheet AA-2106. Fifty-five field storage units (FSU) are located on the road net. Storage is open or hasty. An ASP should stock about 3-5 days of issue by doctrine. The issue day programmed is on the high side, so 3 days stockage was planned. When the TR's described above are totaled for 3 days, a stockage of 5200 tons is determined. This was divided among 63 DODAC lines to be found in all six categories of storage. The most compact storage by regulation is described in Table 2.

TABLE 2

ASP Storage Limits

<u>Storage Category</u>	<u>Tons</u>	<u>Max. Tons per FSU</u>	<u>FSU Required</u>
A	436	400	2 (1)
B	3594	400	9
C	217	300	2 (1)
D	54	400	2 (1)
E	417	50	10
F	<u>394</u>	60	<u>7</u>
Totals	5112		32

Applying a rule that every DODAC line would be placed in two separate FSU locations for dispersion, the number of FSU used for the 63 DODAC lines became 46 with 9 being empty for this simplified program. The mileage of the loop within the ASP is about 12.5 km (7.5 miles) plus some spurs, so the old quantity-distance rule of 800 to 1000 tons/mile of road is easily met.

It was necessary to construct a master inventory deck of DODAC lines and a locator file to be used to make out the DA Form 3151-R, the Ammunition Stores Slip, which guides the loading of the individual vehicles (2).

Supply Bulletin, SP 38-26, Ammunition Supply Rates, contains about 150 DODAC lines. An ASP will stock most of these (except perhaps some pyrotechnic and engineer demolition items) plus a few rockets and small guided missiles not included in the supply bulletin. The master inventory deck constructed has about 130 lines, half of which will be inactive for play purposes. Lot numbers were ignored in maintaining the master inventory. The locator deck considers lot numbers only in the cases of major caliber tank gun ammunition; semifixed artillery ammunition; propelling charges for separate loading ammunition; and guided missiles. This choice was made primarily for reasons of performance (ballistics). Size of lot played was

determined by asking the RAM Division of AMSAA for war reserve lot size data on the types desired and filling the gaps by inquiry of the US Army Missile Command. The locator deck was considered split in two with about an equal number of cards in each subdeck. Since the file included only active DODAC lines in the ASP, there were a total of 150 cards or about 75 per subdeck.

The sequences of operations for issuing ammunition are listed in Table 3, which shows the flow from the supported battalions through the DAO to the ASP, and back to the supported units.

TABLE 3

Model Sequence

 3. Continues to ASP
 4. Inprocesses paperwork
 5. Vehicles proceed to pads
 6. Vehicles loaded
 7. Return to Assembly Area
 8. Outprocess paperwork
 9. Return to Bn trains
-

The procedures for issuing ammunition begins when an ammunition convoy of the using unit arrives at the ASP. The convoy is directed to the vehicle holding area by ASP traffic control personnel. The vehicles are inspected by technical support personnel for compliance with safety standards.

The convoy commander proceeds to the ASP operations office where he submits his transportation order for ammunition to the chief clerk in the stock records section. The order is checked against the stock location and lot records to determine the issuing storage magazines. The stock clerks prepare an ammunition stores slip for each vehicle in the convoy. The stores slip lists the DODAC and FSN, the lot number, the number of rounds and containers and the storage locations from which the items are to be issued. The chief clerk assigns an ammunition checker to each truck or group of trucks going to the same storage magazines. The clerk arranges for the labor and material-handling equipment (MHE) required for loading.

The checker assigned to each vehicle or group of vehicles guides the driver(s) to the proper storage location(s). The checker supervises the loading of the ammunition and verifies the type, lot number, condition and quantity received. When loading is complete, the vehicle proceeds to the vehicle assembly area where it waits for the remaining vehicles in the using unit's convoy. The ammunition received is verified at the ASP operations office. The stores slips are posted to the stock records. Once

verification is completed for all vehicles, the loaded convoy is released from the ASP.

So far as operational play was concerned, the company personnel were split into two 12-hour shifts. This allowed the ASP office to be adequately manned for the clerical operations, the MHE to be manned around the clock, and left 45 men from the magazine platoons available for use as checkers and/or labor on each of the two shifts. All truck drivers from the drawing unit were considered available as labor. Checkers were considered as labor if less than 10 boxes were to be hand loaded at any one field storage unit (FSU) location.

Internal play considered the ASP to be fully stocked at time zero (start of the simulation). Only the issue procedure was played. No resupply or warehousing (unlikely) were played. In the office, no inventory adjustments were played. Neither was the daily status of stocks report played. As an addendum to the TR, the using unit was considered to bring with it the desired loading of each vehicle in the convoy (commodity loaded), so that the ASP office did not have to figure that out. Neither did the ASP office keep any book on issues against available supply rate (ASR) by unit. MHE availability was 100%. The 24 MHE assigned to the Ammunition Company are assigned to one FSU or a small, group of adjacent (bloc of) FSU. MHE do not move long distances between work sites. The program is such that if two or three MHE are assigned to a bloc of FSU, they are utilized in sequence by arriving vehicles before formation of a queue of vehicles waiting to load; however, no more than two MHE's may be loading at the same FSU at the same time.

The ASP has a vehicle holding area for arriving convoys to wait while inprocessing is accomplished and a separate vehicle holding area for the loaded vehicles to reassemble into unit convoys before returning to their battalion trains areas.

In summary, the simulation model including the composition and layout of the ASP, the supported units and the resupply demand on the ASP have been described. In the next section, the resupply procedures used in the model are described in greater detail. Finally, the "Results" section describes the statistical results of the simulation.

METHOD

The operations of the ASP are simulated by the flow of customers between service facilities from the input side (i.e., convoy arrival) to the output side (i.e., convoy departure). The customer units vary from facility to facility, and in most cases, the customer must have reached prior stations before passing to the next one. The customer enters the service facility when it is not busy. Otherwise, the customer joins a queue and waits until he has moved up to the service point on a first-in, first-out queue discipline basis.

The incoming vehicles are inspected in the holding area. The convoy commander passes to the inprocessing office with his paperwork. There, the TR is processed in turn by the head clerk, a master file clerk and the locator file clerk. The clerks assign the trucks (and chits) and any needed laborers and checkers. The checker leaves the holding area with the vehicles (once they complete inspection) and laborers for the magazine area. The vehicles are loaded at the appropriate FSU by the laborers and/or MHE's in the magazine section. The loaded trucks are released to the convoy commander after the operations office has verified the issued ammunition.

The above customer actions and service facilities have been separated into the following time-oriented sequence of steps:

1. The battalion dispatches a convoy to the ASP via the DAO. The departure time is a random variable with a spread of 30 minutes centered about the convoy departure times given by Table 1. Initially, all units forward a convoy between BMNT (beginning morning nautical twilight) and BMNT plus 30 minutes.

2. The arrival time of the convoy at the holding area of the ASP is computed from the travel distance and a random travel speed of 30 km/hr plus or minus two standard deviations (ISD) for daylight or $15 \pm 2SD$ km/hr for nighttime.

3. The inspectors from the ASP make a safety check of the incoming vehicles. The average inspection time is 5 minutes.

4. The convoy commander proceeds immediately upon his arrival to the ASP office with his TR and truck loading papers. The travel time is fixed.

5. The TR is processed through the ASP office in several stages:

- a. The chief clerk scans the TR and associated papers for general completeness.

- b. The master file clerk takes the TR and posts as a debit to the appropriate DODAC cards in the master inventory.

- c. The locator deck clerks receive the TR and truck loading addendum from the master inventory clerk. The truck loading addendum has been written up by the unit by DODAC in terms of pallets and/or boxes for each truck. Using this addendum (and the TR), the locator clerks write the individual DA Form 3151 (Ammo Storage Slip) for each truck, considering lot numbers where appropriate and FSU location. They also post the issues on each DODAC locator card by lot number and FSU. The two clerks work as parallel but independent service points as directed by the master file clerk.

- d. The locator desk clerk passes the sheaf of Forms 3151 to the noncommissioned officer (NCO) in charge of assigning checkers and laborers. The assignment NCO scans the deck of Forms 3151 and assigns a checker to one or more trucks (one or more Forms 3151) and also assigns zero to two laborers to the checker.

6. The checker, truck(s), and laborers proceed to the first FSU in his stack of Forms 3151 (a known measured mileage) at $15 \pm 2SD$ km/hr for daylight or $8 \pm 2SD$ km/hr for nighttime.

7. Using MHE available at the FSU, pallets are loaded. Stochastic loading times are used. Using laborers available, individual boxes or containers are loaded. Four minutes per laborer per box was used (7 tons lift-man/day). Loading is sequential for a checker. Queues form when MHE is not available. If labor loading can be done while awaiting MHE, it is done. Upon completion of loading at first FSU, the checker with his trucks and laborers proceeds to the next FSU and repeats process (steps 6 and 7).

8. The checker, truck(s), and laborers proceed to the convoy reassembly area (known mileage) at $15 \pm 2SD$ km/hr (daylight).

9. Checker and laborers walk to ASP office (15 minutes). Checker turns sheaf of annotated Forms 3151 over to ASP office chief clerk. (It is assumed there are no major discrepancies and no need to correct inventory or locator files.) Checker reports to assignment NCO. Laborer reports to assignment NCO. Both are picked up in available pool.

10. Convoy commander picks up checker (and laborer) with last truck(s) arriving at reassembly area and drives him to ASP office (1 km at $15 \pm 2SD$ km/hr). Checker and laborer same routine as step 12.

11. Convoy commander clears TR with ASP office chief clerk, gets annotated copy, and receipts copy left at ASP. Returns to convoy and departs.

12. Convoy returns to battalion trains area by most direct route (measured) at $30 \pm 2SD$ km/hr for daylight and $15 \pm 2SD$ km/hr for nighttime. Arrival time for convoy is recorded.

The service times for the office clerks in step 5 were determined by two experienced subjects (retired military personnel) who timed themselves while they processed the paperwork for each unit. These times are considered fixed without random variation for the present until appropriate stochastic data can be collected.

The simulation program is separated into two parts, the user's program and the GASP supporting routines. The user's portion specifies the customer traffic flow within the ASP and the mechanisms of the service facilities. The GASP supporting routines are called upon to do bookkeeping tasks such as ordering time events, random number generation, statistical computations and preparing summary reports.

The GASP routines maintain a file of ordered time events. As each new time event is added to the file by the user's program, the file is reordered according to the time of occurrence. The file stores attributes as well as the time of occurrence of the event. These are an event coding denoting what type of event has occurred, and the using unit's convoy and if appropriate, the truck or checker for which the service event took place. These attributes are assigned by the user's program and are stored by the GASP routines.

Once program control is passed to the GASP support routines, the next time event is removed from the file along with the associated attributes. The GASP routine returns control to the user's subroutine, EVENTS, along with the event coding. The subroutine, in turn, calls upon the appropriate user's subroutine to service the event according to the event code. The event attributes of the convoy and truck identifiers are used by the subroutines to locate the information needed for servicing. Table 4 lists the various events with their coding which can occur in this simulation.

TABLE 4
Simulation Events

Code	Event	Figure
1.	Convoy leaves unit	-
2.	Convoy arrives at holding area	2
3.	Safety inspector completes vehicle inspection	3
4.	Convoy commander at inprocessing office	4
5.	Chief clerk completes TR service	5
6.	Master file desk completes service	6
7.	Locator file clerk completes service	7
8.	Checker released from holding area with trucks	8
9.	Checker completes road trip to ammunition pad	9
10.	Loading service completed at ammunition pad	10
11.	Checker arrives at convoy assembly area	11
12.	Checker arrives at operations office	12
13.	Convoy commander at outprocessing office	13
14.	Clerk completes outprocessing service	14
15.	Convoy arrives back at unit	-

The figures (2 through 14) referenced by Table 4 show flow-charts of the steps for the processing of the events. Each figure corresponds to a subroutine in the program which processes one of the time events. In all cases, the subroutine either adds the unit to be serviced; i.e., convoy representative or trucks, to a waiting queue or computes a service time for the unit and adds the service to the event file.

The table and figures show that the program "walks" the convoy representatives and their trucks through the ASP starting at the holding area and ending with the outprocessing. The pattern of passing the next time event to the user's program for servicing and the addition of a new event to the file is repeated until the file is depleted of all events. At this time, the GASP routine computes the statistics of the simulation as called for by the user's program. The next section lists the statistics and results collected for the simulation problem described earlier.

RESULTS AND DISCUSSION

The statistics collected by the simulation program are listed in Tables 5, 6 and 7. Table 5 lists the observed-time statistical variables. The average value and standard deviation are computed for these variables. Table 6 lists the time-persistent numeric statistical variables for which the average value, standard deviation, maximum and minimum values are computed. Table 7 lists queue summary statistical variables. The computed values are (1) the average element (Ave Queue), (2) the average wait time before service (Ave Wait), (3) the average service time (Ave Service) and (4) the fraction of time that the facility is idle (Fraction Idle).

TABLE 5

Observed Time Statistical Variables

-
-
- (a) Supply point input to output (ASP) -
 - W/CN, time convoy within ASP
 - A/CN, difference in convoy arrival times
 - D/CN, difference in convoy departure times
 - (b) Inprocessing office (OFI) -
 - W/CC, time convoy commander within office
 - Q/HE, time TR in chief clerk (HC) queue
 - S/HC, service time of chief clerk
 - Q/MC, time TR in master clerk queue
 - S/MC, service time of master clerk
 - Q/LC, time TR in locator clerk queue
 - S/LC, service time of locator clerk
 - (c) Holding area (HLD) -
 - W/TK, truck time within holding area
 - D/CK, difference in checker departure time
 - (d) Loading area (LDA) -
 - W/CK, time checker within loading area
 - Q/CK, time checker in FSU queue for MHE service
 - S/MH, service time by MHE
 - S/LB, service time by laborers

- N/LC, number in locator clerk queue

(c) Holding area (HLD) -

- N/SP, number of inspectors busy in HLD
- N/TK, number of trucks in HLD

(d) Loading area (LDA) -

- N/CK, number of checkers within loading area
- N/LR, number of laborers within LDA
- N/TK, number of trucks within LDA
- N/MH, number of active MHE's within LDA
- N/FS, number of active FSU's within LDA

(e) Convoy assembly area (ABY) -

- N/TK, number of trucks within assembly area

(f) Outprocessing office (OFO) -

- N/CC, number of convoy commanders within office
 - N/OC, number in clerk queue
-

TABLE 7

Queue Summary Statistics

Facility

-
- (a) Loading area -
INSP - inspection station
- (b) Inprocessing office -
NANC - chief clerk
MASC - master clerk
LOCC - locator clerk
CKAG - checker assignments
- (c) Loading area -
FSU - Field storage unit
MHE - material handling equipment
- (d) Outprocessing office
OUTC - outprocessing clerk
-

Table 8 lists the nomenclature of histogram plots (Figures 15 through 21), and Table 9 lists the nomenclature of plot variables (Figure 22).

The statistical results for a 24-hour simulation are listed in Tables 10 and 11. Table 10 lists the results of the observed variables of Table 5 and the results for the time-persistent variables of Table 6. Table 11 lists the statistical results for the queue variables of Table 7.

Figures 15 through 21 show histograms of the frequency of events as listed in Table 9. Figure 15 shows a histogram of the number of trucks in each convoy. Figures 16 through 21 show the queue size of service facilities at the arrival of the next element to be serviced. The facilities are listed in Table 9 and include the vehicle inspection, the head clerk, the master clerk, the locator clerks, the checker assignment roster and the outprocessing office clerk.

TABLE 8

Nomenclature of Histogram Plots
(Figures 15 through 21)

<u>Table</u>	<u>Description</u>
TKS/CONV	Number of trucks in convoy
INSP/QUE	Number of trucks in inspection queue
HC/QUE	Number of TR's in head clerk queue
MC/QUE	Number of TR's in master clerk queue
LC/QUE	Number of TR's in locator clerk queue
CKA/QUE	Number of checker-assignments in queue
OC/QUE	Number of TR's in outprocessing queue

TABLE 9

Nomenclature of Plot Variables
(Figure 22)

<u>Table</u>	<u>Symbol</u>	<u>Description</u>
TKS/ASP	T	Number of trucks in ASP
CON/ASP	C	Number of convoys in ASP
TKS/HLD	H	Trucks in holding area
TKS/LDA	L	Trucks in loading area
TKS/ABY	A	Trucks in assembly area
CC/OFI	I	Number of TR's in inprocessing office
CC/OFO	O	TR's in outprocessing office
CK/HLD	K	Number of checkers in holding area
LB/HLD	B	Number of laborers in holding area

Figure 22 is a plot of ASP-variables at 10-minute increments during the 24-hour simulation. The variables are listed in Table 10 and include the number of convoys and trucks in the ASP, the number of trucks in the holding area, the loading area and the assembly area, the number of TR's in the inprocessing offices, and the number of checkers and laborers in the holding area. The plot shows the dynamic changes which occur between the service facilities within the ASP.

A study of the intermediate program printout shows that the issue operations are completed within 25 hours starting with the arrival of the first convoy in the 24-hour simulation. The statistics listed in Table 10 shows that a convoy arrives at the ASP on an average of every 34 minutes and one departs every 42 minutes. The mean number of convoys within the ASP is 6.0 and the average time that a convoy stays within the ASP is 310 minutes. The mean number of trucks within the ASP is 43.1

The mean number of convoy commanders in the inprocessing office is 1.4 and the average time within the office is 72 minutes. The average TR-service time is 2 minutes by the head clerk, 13.4 minutes by the master file clerk, and 29.5 by the locator file clerks. The mean number of TR's in the master clerk queue is 0.33, while those in the locator clerk queue is 0.19. The average stay time in the queues is 21 minutes and 16 minutes, respectively. Table 11 and Figures 17 through 19 show that the average queue length at the arrival of the next TR to be serviced is close to zero for the head clerk and locator clerks, but nearly equal to one for the master file clerk. The clerk positions are idle 96.1 percent of the time for the head clerk, 73.9 for the master file clerk and 71.3 for the locator clerks.

The mean number of trucks in the holding area is 15, and the average stay time is 104 minutes. The average time for inspection is 4.95 minutes. The mean number of inspectors busy is 0.72. The average queue length upon arrival of the next truck to be inspected is 4.89, and the average wait time is 5.8 minutes. The inspection facility is idle 82.7 percent of the time.

The average number of checker assignments is 3.84 while the average wait time for a checker assignment is 30 minutes. The assignment queue is empty only 67.0 percent of the time. The average time between checker departures from the holding area is 10 minutes. The average time between arrivals at the assembly area is 11 minutes. The average number of checkers in the holding area is 12 while the average laborers is 11.

The mean number of checkers in the loading area is 12. The average time that a checker is within the loading area is 158 minutes. Of this time, 64 minutes are spent traveling between loading points (average travel distance is 11 kilometers). The average loading time by MHE's is 24.6 minutes while the labor-service time is 23 minutes. The mean number of laborers in the loading area is 8.9. Roughly one-third of the checkers spent an average of 22 minutes in queue waiting for MHE service. The mean number of trucks in the loading area is 21.9 while the mean number of MHE's loading the trucks is 3.6, and the mean number of active FSU's are 6.9. Table 11 shows the usage statistics for each MHE and FSU in the simulation.

The mean number of trucks in the assembly area is 6.0. The average time spent in the area is 41.0 minutes. The mean number of convoy commanders in the outprocessing office is 0.1 persons. The average time within the office is 5.2 minutes.

RECOMMENDATIONS FOR FURTHER RESEARCH

The following is recommended for further research:

1. The computer model could be expanded to include ammunition receipt operations and the DAO clerical operations.
2. The model assumes that all MHE's assigned to the ASP are operational during the simulation. The effect of MHE downtime and maintenance should be included.
3. The model assumes no changes in personnel performance with simulation time. The effect of fatigue and the change in performance with mission demand (i.e., service queue lengths) should be included.
4. The model could be improved by generalizing the ASP inprocessing and outprocessing office operations to other than commodity load demand.
5. An non-hostile tactical environment is assumed for the ASP operations. The possibility of adverse tactical environments; i.e., enemy rocket or air strikes, forces us to consider the deployment of the ASP into ATP sub-units. The simulation model could be used to study the effects of different assignments in personnel, equipment and doctrine upon mission performance.
6. One interesting application of the simulation model that should be investigated further, is the use of the model and computer-driven graphic displays for training candidate ammunition officers. The trainee could use the displays to specify a deployment of the ASP on the terrain, assign equipment and personnel to tasks, and then use the simulation model to evaluate his proposed solution.

CONCLUSION

A computer-simulation program model has been developed for the issue operations of an Ammunition Supply Point (ASP). The model would be useful in the study of the effects of changes in personnel, organization and equipment upon ASP mission performance. The model simulates the TOE 9-38-H3 Ammunition Company in support of (one-half) a reinforced Armored Division during a determined defense. The ASP layout follows the USAMMCS school solution. The simulation program is written in the Fortram language and uses the GASP simulation programs. Statistics have been included for the evaluation of mission performance.

APPENDIX A
PROGRAM VARIABLES

Program Variables

The variable of the user's program are held in the non-GASP labelled common. The variables determine the characteristics of the ASP and describe the status of the simulation. The common block label areas and the associated variables are listed below:

1. UNITS - common block area variables describe the units supported by the ASP:

- (a) NUNIT, number of units supported by ASP.
- (b) ATITLE, unit nomenclature.
- (c) DGO, distance from unit to ASP via DAO.
- (d) DRTN, return distance from ASP to unit.
- (e) IRSP, roadway speed statistic index.
- (f) ILSP, unit departure time statistic index.

2. BASIC - variables describe the unit's commodity load:

- (a) NBT, number of trucks in the basic load.
- (b) ATKB, type of truck.
- (c) NLB, number of lines on truck chit-sheet.
- (d) ADODB, stock line nomenclature.
- (e) ATYPB, unit of quantity.
- (f) XQTYB, quantity of stock line carried by truck.

3. OFCT - variables are the service time statistics indexes of master file clerk and locator file clerk for inprocessing each unit.

- (a) IATMC, master file clerk service time statistics index.
- (b) IATLC, locator clerk service time statistics index.

4. OFCK - variables are the checker and laborer assignments and the store-slip made up for each unit:

- (a) NCK, number of checker assignments for unit.
- (b) NLBX, number of laborers traveling with checker.

- (c) NTK, number of trucks with checker.
- (d) ITK, identity of each truck with checker.
- (e) NSP, number of loading stops made by checker.
- (f) NFSX, identity of FSU for each stop.
- (g) NTPX, number of pallet loaded at each stop.
- (h) AQTX, pallet stock-line nomenclature.
- (i) NBX, number of boxes loaded at stop.
- (j) NLX, number of loaders (laborers, drivers and checker) used to load boxes at stop.

5. DEMAND - variables describe the using unit convoy arriving at the ASP:

- (a) NS, the number of convoys in the scenario.
- (b) AT, the arrival time of each convoy at the ASP.
- (c) AUNIT, unit-nomenclature of convoy.
- (d) NT, the number of trucks in each convoy.
- (e) ATK, the type of each truck in the convoy.
- (f) NL, the number of line items for each truck.
- (g) ADOD, the DODC-number of each line item for truck.

6. LOAD - variables describe the load of each truck in the convoy:

- (a) ATYP, quantity-unit for line-item.
- (b) XQTY, quantity of line item.

7. HOLDA - variables describe the vehicles in the holding area:

- (a) NIQ, number of vehicles in inspection waiting queue.
- (b) NIC, convoy of vehicles in inspection queue.
- (c) NIT, convoy-number of vehicle in inspection queue.

8. INSP - variables describe inspectors in holding area:

- (a) NIQ, total number of safety inspectors.
- (b) NIS, number of inspectors inspecting vehicles.

(c) MISC, convoy of vehicles being inspected by inspector.

(d) NIST, convoy-number of vehicles being inspected.

9. HOAR - variables describe the holding area-to-office and assembly area-to-office distances and speeds:

(a) DOA, distance from holding area to operations office.

(b) DOS, distance from assembly area to operations office.

(c) IOC, convoy commander speed statistical index.

(d) ICK, checker speed statistical index.

10. CLERKS - variables describe the status of the inprocessing office clerks:

(a) NCH, number of TR's in head clerk queue.

(b) NQH, head clerk busy flag.

(c) NSH, convoy of TR's by position in queue.

(d) NCM, number of TR's in master clerk queue.

(e) NQM, master clerk busy flag.

(f) NSM, convoy of TR's by position in queue.

(g) NCL, number of TR's in locator file clerk queue(s).

(h) NQL, locator file clerk busy flag.

(i) NSL, convoy of TR's by position in queue.

11. STATUS - variables indicate inspection and inprocessing status for each truck in scenario:

(a) ISP, inspection indicator for truck.

(b) ISS, inprocessing indicator for truck.

12. STOCKS - variables describe the office master file cards.

(a) NSL, number of line-items in master file.

(b) ADODC, DODC-number of each line item.

(c) XLIO, quantity of line item in stockage.

(d) XLIR, line item reorder point.

- (e) NLIP, line item reorder flag.
- (f) XLWRD, pound per box of line item.
- (g) XRDBX, rounds per box.
- (h) XBXPL, rounds per pallet.

13. SITES - variables describe the site layout and the distribution of the stockage:

(a) DST, roadway distances among the holding area, the FSU's in the magazine sections, and the assembly area.

(b) IASP, ASP roadway speed statistic index.

(c) NFSU, number of FSU's in magazine section shown on locator card.

(d) NSTACK, number of stacks in each FSU.

(e) ADODX, DODC-number of line item stored in stacks.

(f) ALOTX, lot number of item stored in stacks.

(g) XSQTY, quantity of items stored in stacks.

14. REORD - variable, ITROX, is the reorder time statistics index.

15. STORES-VARIABLES - variables describe the store slips for each truck made out by the inprocessing office:

(a) NLIP, number of stops on store slip for truck.

(b) IFSU, FSU at truck stop.

(c) ISTC, stack within FSU at stop.

(d) XLQTY, quantity of items to be picked up at stop.

16. CKASG - variables describe the checker assignment queue.

(a) NCA, number of checker assignments in queue.

(b) NCT, convoy of trucks in assignment.

(c) NCI, convoy unit number in OFCK file (see Item 4).

(d) NCC, checker number in OFCK file for unit.

(e) NTC, number of trucks in assignment.

(f) NCTT, identity of trucks in assignment.

(g) NLTT, number of laborers in assignment.

17. CHECKER - variables describe the status of the checker personnel:

(a) NGO, total number of checkers assigned to issue operations.

(b) NGH, number of checkers out on pickup.

(c) NGC, convoy of the trucks with a checker on pickup.

(d) NGCT, convoy unit number in OFCK file (Item 4) for trucks with checker.

(e) NGT, checker number in OFCK file for unit.

(f) NGL, MHE use indicator at stop.

(g) NGS, loader use indicator at stop.

18. LABOR - variables describe the status of the laborers:

(a) NHO, total number of laborers assigned to issue operations.

(b) NHL, number of laborers idle.

(c) IRLOAD, labor loading rate statistics index.

19. MMHE - variables describe the status of the MHE's assigned to issue operations:

(a) NMHEO, total number of MHE's on hand.

(b) IMHE, MHE busy flag.

(c) NMHF, number of MHE's assigned to a FSU.

(d) IMHF, identity of MHE's assigned to FSU.

(e) NTYP, type of MHE.

(f) IRMHE, MHE loading rate statistical index as a function of the MHE type, the truck type and the line item type.

(g) IDKE, number of pallet line item in MHE loading information.

(h) ADKE, DODC number of pallet line item.

20. PADS - variables describe the checker queues at the FSU's waiting for MHE service:

- (a) NQP, number of checkers in queue.
- (b) NPC, identity of checker by queue portion.
- (c) NPS, stops number for checker on store slip.

21. CONVOY - variables describe the convoy assembly area:

- (a) NQTO, number of trucks in assembly area for a convoy.
- (b) NQT, total number of trucks in assembly area.

22. OUTPUT - variables describe the outprocessing office:

- (a) NGO, outprocessing clerk busy flag.
- (b) NQO, number of TR's in outprocessing service queue.
- (c) NOC, convoy of TR's by queue position.

APPENDIX B

COMPUTER PROGRAM

Computer Program

The computer program used for the issue simulation is attached below. The program is written in the FORTRAN IV programming language for the CDC 7500 computer system here at the US Army Aberdeen Proving Ground facilities. The program calls upon the GASP IV set of routines which is a part of the supporting programs available. The subroutines supplied by the user in the form of this program are described below:

1. ASP - main program which calls upon the GASP supporting routine to start the simulation.

2. INTLC - subroutine called by the GASP routine to read in the ASP characteristics and the initial conditions of the issue scenario.

3. PLAC - places time event in GASP reference file along with reference information such as event class coding and event identification.

4. EVNTS - called by GASP routine to process next event in event file according to event class coding.

5. LVUNIT - computes time convoy leaves unit and when it arrives at ASP. Called by EVNTS (Event 1).

6. QHOLD - adds using unit's convoy to holding area. Called by EVNTS upon arrival of convoy at the ASP (Event 2).

7. INSP - processes inspection of vehicles. Called by EVNTS at completion of inspection (Event 3).

8. ISRO - adds convoy commander to inprocessing at operations office. Called by EVNTS upon arrival of convoy commander at inprocessing office (Event 4).

9. CCTOS - adds TR to master clerk service at completion of that of head clerk. Called by EVNTS (Event 5).

10. MCTOS - adds TR to locator clerk service at completion of that of master clerk. Called by EVNTS (Event 6).

11. LCTOS - completes and updates locator clerk service. Called by EVNTS at completion of locator clerk service (Event 7).

12. CKFUNC - adds to checker assignment queue at completion of locator clerk service. Called by LCTOS.

13. CASSP - releases checker from holding area with trucks if trucks have been inspected, store slips are completed, and checkers and laborers are available. Called by INSP, LCTOS and CKSRO.

14. TASSP - computes travel time of checker to first stop from holding area. Called by EVNTS upon release of checker from holding area (Event 8).

15. TCRPD - adds truck to magazine loading service. Called by EVNTS upon arrival of truck at magazine (Event 9).

16. TCLPD - finds next stop for checker and computes travel time. Called by EVNTS upon completion of truck loading by magazine (Event 10).

17. TACBA - called by EVNTS upon arrival of truck at vehicle assembly area (Event 11). Forwards checker and laborers to operations office. If complete convoy is in assembly area, the convoy commander is sent to the outprocessing section of the operations office.

18. CKSRO - checks checker-assignment queue for release of trucks to loading area upon return of checkers and laborers. Called by EVNTS (Event 12).

19. COSRO - adds convoy C.O. to outprocessing service at arrival of C.O. at office from assembly area. Called by EVNTS (Event 13).

20. COCMP - releases convoy from ASP. Called by EVNT at completion of outprocessing (Event 14).

21. RELCV - computes convoy return time to unit. Called by EVNT at release of convoy (Event 15).

22. REORD - subroutine computes in-shipment delivery amount and time of arrival of shipment convoy. Called by SSLIP when reorder point is reached in line item inventory.

23. SUPPL - subroutine updates stock inventory records upon receipt of shipment. Called by EVNTS upon arrival of shipment convoy (Event 16).

24. OTPUT - computes queue summary statistics at completion of simulation. Called by GASP.

25. Subroutines used in conversions:

MISC
FDUNIT
CONV
GTMC
GQTY
GTLC

26. Subroutines used in statistical bookkeeping during the simulation:

GPLOTX
EAVT
TIMS
WCOLC
COLC
QSTAT

27. The following are GASP subroutines (slightly modified for our purposes) or functions:

GASP
TIMST
DRAND
RNORM
COLCT
GPLOT
HISTO

28. The data file contains the following:

a. The control data used to initialize the supporting GASP routines; and,

b. The data specifying the size and characteristics of the ASP, and the initial scenario to be simulated.
